

Task B — Prioritized Performance Fixes

J.Crew India Web Performance Optimization

The original mobile Lighthouse/PageSpeed test returned **net::ERR_TIMED_OUT**, so the priority order begins with reliable page loading and critical rendering, then moves to Core Web Vitals, JavaScript, mobile usability, accessibility and delivery optimization.

Priority Summary

Priority	Issue / Goal	Required Fix	Expected Benefit
P0 — Critical	Lighthouse mobile load timeout	Reduce initial workload and ensure the critical page can load reliably.	Allows high mobile Lighthouse conditions to complete.
P0 — Critical	Hero / likely LCP resource	Optimize the hero image using an efficient format, correct dimensions and correct aspect ratio.	Improves LCP and speeds up initial loading of critical hero image.
P1 — High	Below-fold image loading	Lazy-load collection and other non-critical images; use asynchronous loading.	Reduces initial network transfer and speeds first render.
P1 — High	Layout stability	Reserve image dimensions using width/height or aspect-ratio.	Reduces layout shifts and improves CLS.
P1 — High	Non-critical JavaScript	Remove unnecessary dependencies and defer optional interactions.	Reduces main-thread work, parsing and blocking time.
P1 — High	Critical DOM/render path	Keep component structure focused and avoid excessive nested components.	Reduces style, layout and rendering work.
P2 — Medium	Mobile navigation	Use a responsive mobile-first navigation and avoid loading unnecessary scripts.	Improves mobile usability and reduces initial complexity.
P2 — Medium	Third-party resources	Audit analytics, marketing, fonts and other external resources; defer non-essential requests.	Reduces essential requests and third-party execution cost.
P2 — Medium	Accessibility	Use semantic landmarks, alt text, accessible labels, keyboard focus and ARIA roles.	Improves accessibility scores and document usability.
P2 — Medium	Agentic Browsing	Review accessibility-tree quality, layout stability and agent-facing content.	Improves agentic agent-oriented page loads.
P3 — Lower	Caching and delivery	Configure CDN delivery, compression and long-lived caching for static assets.	Improves static assets and production asset delivery.

Recommended Implementation Order

Phase 1 — P0: Fix reliable loading and optimize the hero/LCP resource first. These have the highest impact because the original test could not complete.

Phase 2 — P1: Implement lazy loading, reserve image dimensions, reduce unnecessary JavaScript and simplify the critical rendering path. These changes directly target loading speed, blocking time and layout stability.

Phase 3 — P2: Improve responsive navigation, reduce third-party overhead, strengthen accessibility and rerun agent-oriented checks once the core page is stable.

Phase 4 — P3: Apply production caching, CDN and compression settings after deployment.

Success Criteria

The optimized deployed version should complete the mobile PageSpeed test successfully, return measurable FCP/LCP/TBT/CLS/Speed Index values, and aim for green Core Web Vital thresholds. Final scores should be recorded only after testing the deployed build.
